Let worms eat your food waste. They will happily turn it into some of the best fertilizer on earth. Worm compost, otherwise known as worm castings or vermicomposting is a fascinating, fun and easy way to recycle your food scraps. A worm bin requires very little work, produces no offensive odors and provides worm castings that help plants thrive. Composting with worms saves money on garbage bills, improves the fertility and waterholding capacity of garden soil, benefits the environment by recycling valuable organic materials, and helps solve the crisis of limited landfill space.

Getting Started

Only a few things are needed to make a good worm compost bin: a container, bedding, worms and worm food (your kitchen waste).

Worms Bins
You can use a plastic storage bin, a shipping crate, a commercial worm bin or a homemade wooden bin. Bins should be 8-14 inches deep and have a tight fitting lid to keep out rodents and birds. Drill 1/4 inch holes in the bottom, on the top and sides, 5-7 inches apart, to provide ventilation and drainage. Set the bin on supports so excess moisture can drain out.

Hardware and discount stores carry an assortment of plastic storage containers that can be made into bins or you can reuse an extra container you might already have laying around. Ultraviolet light is toxic to worms, so bins should be made from an opaque material. The rule of thumb for bin size is two square feet of surface area per person, or one square foot of surface area per pound of food wastes generated each week. Vegetarians often find they need a bin with four square feet of surface area per person.

Where to Put the Bin
The ideal temperature for compost worms is 59-77 degrees F. Place your bin in the shade or in an area where it will only receive limited morning light and, if possible, under a tree or an overhang to protect from frost. Make sure rainwater cannot enter the bin through the lid. As long as outdoor temperatures are between 30 and 90 degrees and you have at least 4 inches of moist bedding in the bin, your worms should be fine. Good spots for your bin:

- Under a tree
- Along side of house
- Garage
- Patio or deck
- Under the eaves
- Shed

Bedding Materials
The compost worm’s natural habitat is in piles of fallen leaves or manure. You will need at least four inches of bedding to keep the worms cool and moist, to give them fiber to eat and to discourage fruit flies from getting into the food.

For best results, make bedding from a mixture of materials, including shredded, non-glossy newspaper, brown leaves (no pine, redwood, aromatic leaves or leaves with tannins), straw, sawdust, shredded corrugated cardboard, finished compost, well-rotted and rinsed horse manure and coconut pith fiber (available from nurseries).

A handful of soil provides microorganisms and grit to help the worms grind their food. For results, make bedding from a mixture of materials, including shredded, non-glossy newspaper, brown leaves (no pine, redwood, aromatic leaves or leaves with tannins), straw, sawdust, shredded corrugated cardboard, finished compost, well-rotted and rinsed horse manure and coconut pith fiber (available from nurseries).
Worms

Compost worms are called "red worms" or "red wigglers." They are often found in old compost piles, but are different from the earthworms you normally find in the ground. Their scientific names are *Eisenia fetida* and *Lumbricus rubellus*.

These worms have a big appetite, reproduce quickly, and thrive in confinement. They can eat more than half their own weight in food every day! Common earthworms and nightcrawlers don't survive well in bins, since they normally live below the soil surface. When purchasing red worms, one pound is all you need to get started. For sources, see "Where to Buy Worms."

Feeding the Worms

Worms like to eat many of the same things we eat, only they aren’t as picky. Stale bread, apple cores, lettuce trimmings, coffee grounds, and nongreasy leftovers are just some of the foods we usually discard that worms love.

**Do Feed**

1. Vegetables Scraps
2. Fruit Scraps and peels (mold/rot is fine)
3. Bread and grains
4. Tea bags
5. Non-greasy leftovers
6. Coffee grounds & filters
7. Crushed egg shells
8. Napkins, paper towels

**Do Not Feed**

1. Meats, fish
2. Greasy foods
3. Dairy products
4. Twigs and branches
5. Dog, cat, or bird feces
6. Overripe or moldy foods
7. Fruits with pit or bones
8. Non-natural foods

The first feeding is like stocking an empty refrigerator. Start your worms out with 2-3 quarts of scraps. Include some chopped up soft food (melon, grapes, cooked vegetables) or somewhat rotted foods that will decompose quickly. After the first feeding, feed the worms weekly, starting out with about a quart of food scraps per week.

As they multiply, you can add larger quantities of food scraps. After a few months you can add an inch of food scraps each week. To avoid fruit flies and odors, bury food under top layer of the bedding. Don’t dump and run!

Worms prefer smaller-sized scraps and will eat through them more quickly than large or whole pieces of food. If your worm bin starts to smell bad, it could be a sign that you are adding more food than the worms can process. If too much food is added, it can even heat up and kill the worms!

Quit feeding for awhile and when most of the food has been eaten, start feeding again.

**Troubleshooting**

<table>
<thead>
<tr>
<th>Problems</th>
<th>Causes</th>
<th>Solutions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Worms are dying</td>
<td>Too much food in bin, starting to heat up like hot compost</td>
<td>Feed less food or less often or get another bin</td>
</tr>
<tr>
<td>Bin attracts ants</td>
<td>Too dry</td>
<td>Add water until slightly damp</td>
</tr>
<tr>
<td>Bin attracts flies</td>
<td>Too wet</td>
<td>Add dry shredded paper</td>
</tr>
<tr>
<td>Bins outside away from people</td>
<td>Food exposed</td>
<td>Bury food completely</td>
</tr>
<tr>
<td>Spring fruit fly invasion</td>
<td>Feed less fruit, put bin outside away from people</td>
<td></td>
</tr>
</tbody>
</table>

**Where to Buy Worms**

Buy worms and finish vermicomposting at the Salinas Chinatown Community Garden. Visit the website for contact information.

Maintaining Your Worm Bin

Add fresh bedding every few weeks. Always keep a two-inch layer of fresh bedding over the worms and food in your bin. Shredded, nonglossy newspaper works great! Keep bedding a little wetter than a wrung out sponge. In a plastic bin, add dry bedding to absorb excess moisture. You may need to sprinkle the contents of wooden bins to moisten them occasionally.

**Method #1:** Most of the uneaten food, bedding, and worms will probably be in the top third of your bin. Remove this material, worms and all, and put it aside to start a new bin. Remove the remaining material from the bin for use as compost. Put the uneaten food, bedding and worms back in the bin, and resume feeding and maintaining your bin.

**Method #2:** This method works only in bins over three feet long. Move the contents of your worm bin to one side, place fresh bedding in the empty space and bury your food wastes there for a few months. Harvest the other side after most of the worms have moved into the new food and bedding.

**Method #3:** Spread a sheet of plastic out in the sun. Dump the contents of the worm bin and build a few cone shaped piles on the sheet. Gently remove the top layer of each pile until you see worms. To escape the light, the worms will dive deeper into the piles. After repeating the process every 20 minutes or so for a few hours, you will be left with a wiggling pile of worms. Return the worms to their bin with some of the compost for bedding.

Using Your Worm Compost

Using your finished product will help your plants thrive by adding plant growth hormones, beneficial microorganisms, humus and nutrients to the soil.

Vermicompost is lumpy and clay-like when removed from the bin. You can use it right away or let it sit in an open plastic bin or bag away from rain and sun for 1-4 months to transform into a fine-grained product. Sprinkle a layer at the base of indoor or outdoor plants, making sure compost is not piled up against plant stems. Cover with soil or mulch. You can also blend worm compost up to 20% into potting mix or garden soil.

Harvesting Worm Compost

After you have fed your worms for 3 to 6 months, you’ll see some worm compost in the bottom of your bin. You can harvest what’s there, or wait until your bin is nearly overflowing. No matter which method you use, some worms will remain in the compost. Worms put in the garden with the compost will not live long, but your main goal is to reserve enough worms to re-start your bin. You can’t save every worm! Here are a few methods for separating the worms from the compost.

1. Sowbugs, beetles, other critters in bin
2. These are good for your compost!
